exe file you run. For example, you could use Windows Activation Technologies, or you could use a serial number. \*Tip: The validation is required by the software publisher and is not optional. However, your users must not be able to install your product without a valid license key.\* Activation requires a valid \*product license key\*. This key can be obtained at any time and is associated with the license version and installed product. You can use the URL of the activation web page to obtain the product license key in the source code, but the web page is not mandatory. To install the software, run the setup program. The setup program displays an installation screen with the product activation as an option. [Setup] ... [Screen] [Prompt] [Question] [Answer] [Selection] [Settings] [Finished] The **\*\*Finished\*\*** message is displayed when the user selects the product activation option. When the setup program detects that the product license is valid, it proceeds with the installation. Q: How can I calculate the openGauss distance between two nodes in a directed graph? I have an undirected graph, with edges and nodes. How can I calculate the distance between nodes in the graph? A: The Laplacian Matrix The Laplacian Matrix is the difference between the adjacency matrix and the graph transpose. In your case, the Laplacian is equal to  $L - D^T$ , where  $D$  is the degree matrix. You can calculate this using the Graph class. The distance between two nodes can be found with the distance method of the Graph object. For instance, the following will return the distance between the nodes A and B: >>> G = (graph.Graph()).add\_nodes\_from([n1, n2, n3, n4], name='nodes',
