

Docking Windows are Java's answer to the Windows problem. They can contain Swing Components and can contain non-Swing components such as files, links, database connections etc. Docking Windows provide the user with a way of arranging their application in various layouts. Split windows are used to create the separation between the docked Swing components and the desktop. Tab windows are used to combine Swing components into a single view and tabbed panel. Floating windows are used to provide the user with a window that can be moved anywhere on the screen. Docking Windows include a built in tabbed panel component that can be customized by setting the tab order and adding new tabs and components to the panel. The properties that can be set for the tabbed panel include: * Minimum size * Maximum size * Number of rows * Number of columns * X location * Y location * Orientation * Component Properties * Properties window to set properties for individual components (TinyFox edit framework) * Setting for the right click context menu (TinyFox edit framework) The application can be packaged into small sized jar files (containing all Swing components) or can contain any non-Swing components and files. All communication with the hosting application is achieved by the AWT Events mechanism. This means that there is no need to have complicated event handlers written for specific application scenarios. The application can be used with any application that uses the AWT event model. ----- Add this library to your project using the following commands in your project's build.xml file. /WEB-INF/lib/jswing-1.1.1.jar /WEB-INF/lib/jswing-i18n-1.1.1.jar If you want to load the classes from this library on the class path, you need to add this section of code to your build 70238732e0
